Influence of Lithium on Growth and Viability of Thyroid Follicular Cells

(lithium / FRTL-5 / 3H-thymidine incorporation / 51Cr release)

Abstract. Lithium accumulates in the thyroid gland and can cause goiter or thyroid dysfunction. The aims of our work were: 1) to verify whether lithium stimulates proliferation of thyroid cells; as methods, the 3H-thymidine incorporation assay and the MTT assay (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide) were used; as a model system the FRTL-5 (Fischer rat thyroid cells in low serum) cell line was selected, 2) to test whether lithium can have a cytotoxic effect on FRTL-5 cells, using the cytotoxicity assay with 51Cr release and the trypsan blue exclusion method. Without TSH stimulation, lithium at 0.35–2 mM concentrations significantly increased the 3H-thymidine incorporation. A similar effect was observed in the case of the MTT assay: without TSH stimulation, lithium at 0.4–2 mM concentrations showed a significant stimulation of proliferation. Surprisingly, under TSH stimulation, lithium at the 2 mM concentration significantly inhibited proliferation of FRTL-5 cells. With the cytotoxicity assay, lithium was found to increase 51Cr release at 1.4–2 mM concentrations. Additionally, the percentage of viable FRTL-5 cells at 0.35–2 mM concentrations of lithium was lower than in the controls without lithium. In conclusion, lithium was found to stimulate proliferation of FRTL-5 cells in conditions without TSH and, surprisingly, lithium in higher concentrations diminished proliferation of FRTL-5 cells under TSH stimulation. A cytotoxic effect of higher lithium concentrations was observed.

Lithium as lithium carbonate has been widely used in treatment and prophylaxis of recidivant bipolar affective disorders in therapeutic concentrations between 0.5 mM and 1.2 mM (Rosenthal and Goodwin, 1982; Schou, 1989; Kallner and Petterson, 1995). Intrathyroid concentrations of lithium can be 2.5–5 times higher than its serum concentrations (Salata and Klein, 1987). Lithium therapy has been associated with higher incidence of goiter (Schou et al., 1968; Lazarus and Bennic, 1972; Perrild et al., 1990; Boccheta et al., 1996), hypothyroidism (Lindstedt et al., 1977; Leroy et al., 1988; Yassa et al., 1988; Clower, 1989), and, rarely, hyperthyroidism (Rosser, 1976; Barclay et al., 1994). In vitro lithium inhibited iodine uptake, coupling of iodothyrosines, and release of thyroxine and triodothyronine (Bhattacharyya and Wolff, 1976; Davies and Franklyn, 1991). In vitro lithium increased 3H-thymidine uptake in porcine primary cultures and in FRTL-5 cells (Urabe et al., 1991). Additionally, some cases of lithium-associated thyroiditis have been reported. A cytotoxic effect of lithium has been assumed (Kontozoglou and Mambo, 1983). Presumably, the cytotoxic effect of lithium has not yet been tested in vitro.

The first aim of our work was to verify whether lithium had a mitogenic effect. For this purpose we used the 3H-thymidine incorporation assay and the MTT assay. The second aim was to test whether lithium could have a cytotoxic effect on FRTL-5 cells. We used the cytotoxicity assay with 51Cr release and the trypan blue exclusion assay for cell viability estimation.

Material and Methods

Cell culture

The experiments were performed using the FRTL-5 cell line (Ambesi-Impimbato et al., 1980). FRTL-5 cells maintain most of the differentiated functions of normal thyroid cells but are unable to organify iodide.

FRTL-5 cells were grown in a Coon modified Ham F-12 medium (Sigma Chemical Co., Deisenhofen, Germany) supplemented with 5% calf serum (Gibco BRL, Paisley, UK) and a six-hormone mixture consisting of insulin (10 μg/ml), transferrin (5 μg/ml), hydrocortisone (0.36 ng/ml), somatostatin (10 ng/ml), glycyl-L-histidyl-L-lysine acetate (2 ng/ml) and thyrotropin (1 mU/ml), all purchased from Sigma Chemical Co.

Cells were grown in a Heraeus-CO2-auto-zero incubator (Heraeus Instruments, Hanau, Germany) in an atmosphere of 5% carbon dioxide and 95% air at 37°C, 100% of humidity.
**3H-thymidine incorporation: growth assay**

The quantity of 6.7 x 10⁴ FRTL-5 cells were seeded in 24-well plates. They grew for 3 days in the six-hormone medium and, for further 7 days, in the five-hormone medium (medium without TSH). The final volume of the culture medium was 500 μl. The wells were then washed once with the five-hormone medium. Lithium carbonate (Fluka Chemie, Buchs, Switzerland), dissolved in the five-hormone medium, was added in the following concentrations: 0 mM (controls without lithium), 0.35 mM, 0.7 mM, 1 mM, 1.4 mM, 1.7 mM and 2 mM without TSH and with 1 μU/ml of TSH. Maximal cell lysis was achieved by incubating cells with the detergent NP 40 (20% solution). The plates were incubated for 24 h at 37°C in the incubator. Aliquots of supernatant were measured in a gamma-counter. The percentage of specific lysis was calculated according to the formula: \([\text{cpm (lithium + medium)} - \text{cpm (medium alone)}]/\text{cpm (medium alone)}\] x 100 (Chiovato et al., 1994).

**Trypan blue exclusion method**

Suspension of FRTL-5 cells in HBSS with different lithium concentrations (0 mM, 0.35 mM, 0.7 mM, 1 mM, 1.4 mM, 1.7 mM and 2 mM) was mixed with a 0.4% solution of trypan blue (Sigma Chemical Co.). Five to fifteen minutes later, coloured (non-viable) and dye-excluding (viable) cells were counted in the Bürker-Türk’s chamber. The results were expressed as a percentage of viable cells according to the formula: [number of viable cells (non-coloured)/number of all cells] x 100 (Chiovato et al., 1994).

**Statistics**

The results of experiments are the averages of quadruplicate determinations ± SD on two occasions and have been statistically analysed using analysis of variance and the t-test.

**Results**

The influence of lithium on ³H-thymidine incorporation into FRTL-5 cells in the absence of TSH stimulation is shown in Figure 1. Lithium at 0.7 mM, 1 mM, 1.4 mM, 1.7 mM and 2 mM concentrations significantly stimulated ³H-thymidine incorporation when compared with the controls without lithium.
